

Unemployment rate

- Important rates in an economy: interest rate, exchange rate, inflation rate, and unemployment rate.
- Employment = number of people having a job.
- Unemployment = number of people not having a job but looking for one.
- Labour force = Employment + Unemployment
- Unemployment rate = $\frac{\text{Unemployment}}{\text{Labour force}}$
- Participation rate = $\frac{\text{Unemployment}}{\text{Economically active population}}$

Unemployment

Basic types of unemployment

- Actual unemployment is divided into three categories (the first two define “natural unemployment”).
- Frictional. Occurs while workers are changing jobs.
- Structural. Due to structural changes in the economy that create and eliminate jobs and to the institutions that match workers and firms (firing and hiring costs, minimum wages, unemployment benefits, mobility restrictions, lack of training...).
- Cyclical. Generated by the short-run fluctuations of GDP (rises with recessions, falls with booms).

13

Unemployment

Okun's law

- Okun's law is an empirical relationship suggested in 1962 by the US economist Arthur Okun (1928-80).
- Okun's law: there is a negative relationship between the change $\Delta u = u - u_{-1}$ in the unemployment rate and $y = \frac{Y - Y_{-1}}{Y_{-1}}$, the rate of growth of real GDP Y . A simple formal expression of the law is

$$\Delta u = a - b \cdot y$$

where a and b are positive constants that depend on the economy considered and the period with respect to which the variables are measured.

14

Unemployment

Okun's law (US version) /1

- Expressing the variables as annual percentages, in the US, $a \approx 1.5$ and $b \approx 0.5$. Therefore:

$$\Delta u = 1.5 - y/2 \quad \text{or} \quad u = u_{-1} + 1.5 - y/2.$$

- a represents the increase in u that occurs when the economy does not grow: if $y = 0$, then $\Delta u = a$.
- For instance, if $u_{-1} = 2\%$ and $y = 0$, then $u = u_{-1} + a - y/2 = 2 + 1.5 - 0/2 = 3.5$. Hence, if the unemployment rate at the beginning of the year is 2% and the economy does not grow, at the end of the year the rate is 3.5%.

15

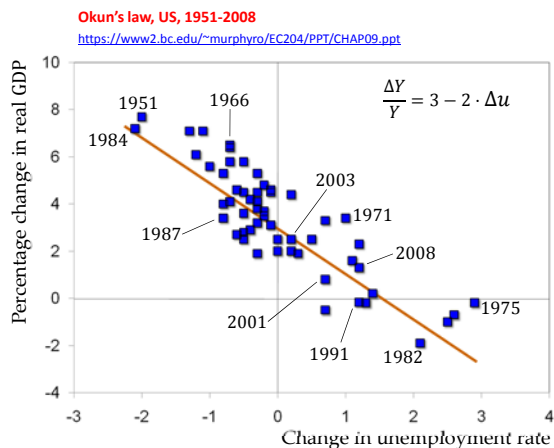

Unemployment

Okun's law (US version) /2

- b measures the ability of the economy to transform GDP growth into a smaller unemployment rate: $b \approx 0.5$ means that increasing y by one point reduces u by 0.5 points.
- If $y = 2\%$, then $u = u_{-1} + 1.5 - y/2 = u_{-1} + 1.5 - 2/2 = u_{-1} + 0.5$. If $y = 3\%$, then $u = u_{-1} + 1.5 - y/2 = u_{-1} + 1.5 - 3/2 = u_{-1}$.
- Therefore, increasing y from 2% to 3% reduces u from $u_{-1} + 0.5$ to u_{-1} . There is a gain of 0.5 points: an additional 1% in y becomes 0.5 points less of u .

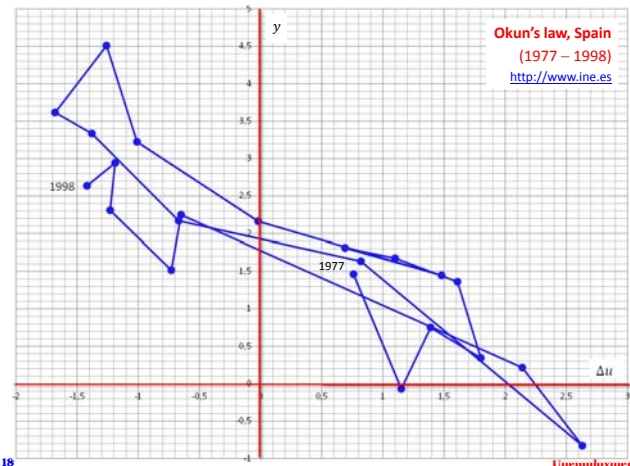

16

Unemployment

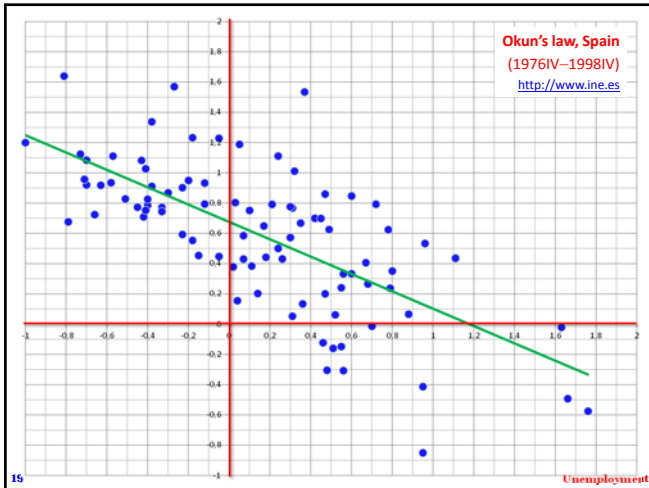

17

Unemployment

18

Unemployment

The Phillips curve

- It is an empirical relationship described in 1960 by Paul Samuelson and Robert Solow based on a 1958 paper by the New Zealand economist Alban William Housego Phillips (1914–1975).
- The Phillips curve expresses a negative relationship between the unemployment rate u and the inflation rate π : the lower u , the higher π .
- With α and β positive constants, a linear Phillips curve is represented by an equation of the sort

$$\pi = \alpha - \beta \cdot u .$$

20 Unemployment

Trade-off between u and π

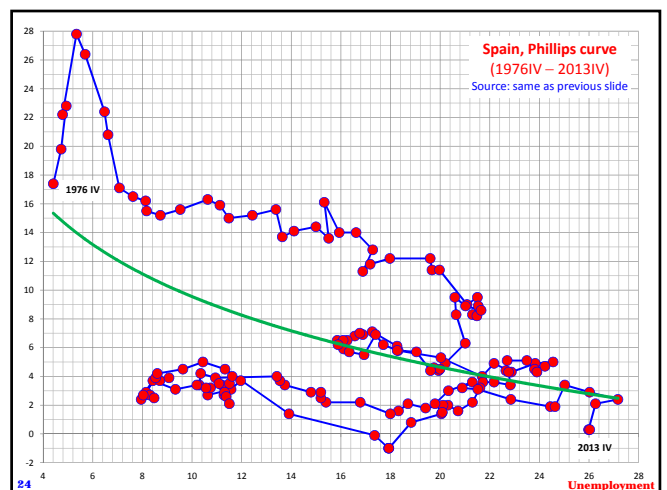

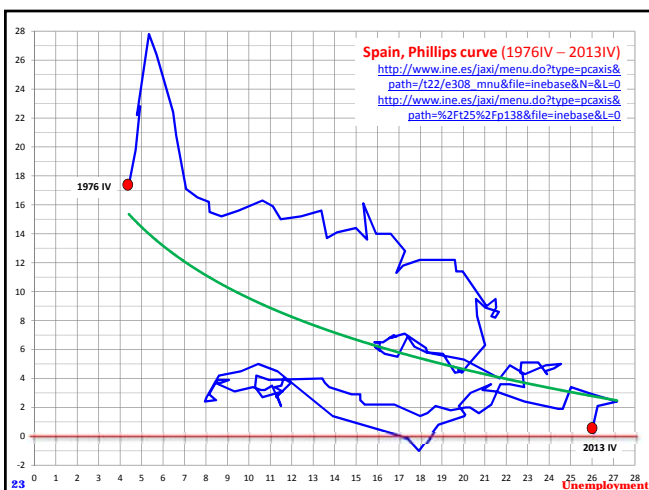

- Expressing π and u in percentage terms, that $\pi = \alpha - \beta \cdot u$ means that, to reduce one percentage point the unemployment rate u , it is necessary to accept an increase in the inflation rate π of β points.
- Let $\alpha = 10$ and $\beta = 2$. If $u = 4\%$, then $\pi = 10 - 2 \cdot 4 = 2\%$. Then, for u to be reduced one point (from 4% to 3%), π must be increased in two percentage points (from $\pi = 2\%$ to $\pi = 10 - 2 \cdot 3 = 4\%$).
- α is the inflation rate that obtains with zero unemployment. It is a measure of underlying inflation.

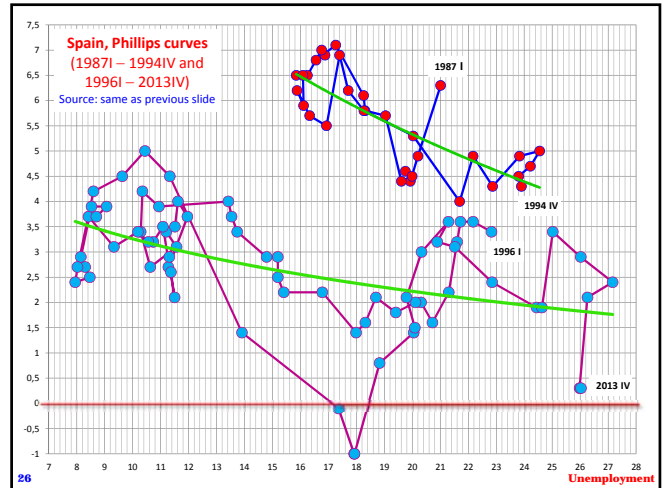

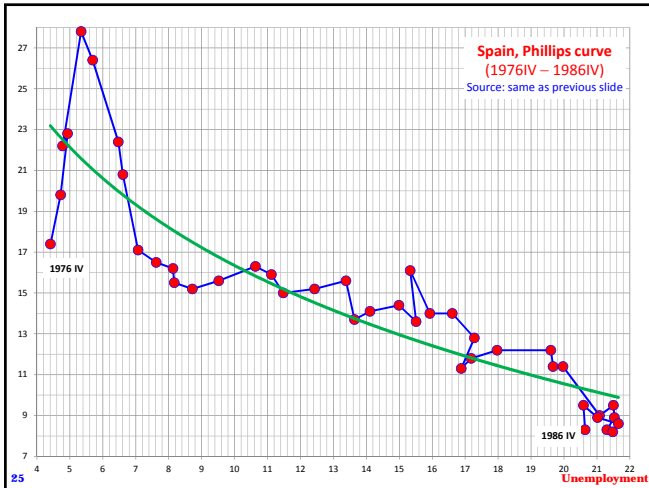

21 Unemployment

Unstability of the Phillips curve

- In contrast to Okun's law, the Phillips curve is in general unstable, since α is a volatile parameter.
- α depends on inflation expectations and the firms' cost structure: an increase in expected inflation or in the production costs rises α . When α rises, the curve shifts upward, so more inflation must be paid to reduce the unemployment rate.
- β indicates how sensitive π is to changes in u . It depends on institutional factors, like the bargaining power of trade unions (more power, higher β).

22 Unemployment

Internal and external balance

- Internal balance requires full employment of resources (sufficiently low unemployment rate) and price stability (low and stable inflation rate).
- External balance corresponds to a balanced current account (the supply and demand for the domestic currency are balanced). For simplicity, external balance is defined as zero trade balance.
- Internal balance and external balance both are assumed to depend on two variables: domestic expenditures and the real exchange rate.

29

Unemployment

The internal balance (IB) function /1

- The IB function drawn on the next slide is assumed increasing for the following reason.
- Suppose the economy is initially at point *a*. If a real appreciation occurs (the real exchange rate increases), then imports rise and exports fall. That is, there is a switch in demand from domestic to foreign goods. As a result, unemployment goes up and the economy moves from point *a* to *b*.
- To restore internal balance by reaching point *c*, unemployment must be eliminated. This requires an increase in domestic expenditure.

30

Unemployment

Interpreting the IB function /1

31

Unemployment

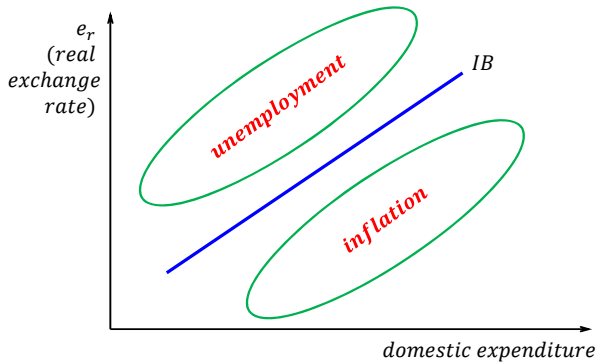

The internal balance (IB) function /2

- It follows from the previous analysis that points above the IB function (excessive expenditure abroad) imply the existence of unemployment.
- Below the IB function failure of internal balance is not due to unemployment but to inflation.
- For instance, at point *d*, given the corresponding real exchange rate e'_r , domestic expenditure is excessive with respect to the level D_a required to reach internal balance. This excess of domestic expenditure manifests itself in the form of inflation.

32

Unemployment

Interpreting the IB function /2

33

Unemployment

The external balance (EB) function /1

- The EB function drawn on the next slide is assumed decreasing for the following reason.
- Suppose the economy is initially at point *a*, where the trade balance is zero. If domestic expenditure increases, GDP and, consequently, income also increase. Part of this additional income is spent buying foreign goods. A trade deficit ensues.
- To restore external balance by reaching point *c*, the trade deficit must be neutralized. This requires a reduction of the real exchange rate: a real depreciation (an improvement of competitiveness).

34

Unemployment

Interpreting the EB function /1

35

Unemployment

The external balance (EB) function /2

- It follows from the previous analysis that points above the EB function (excessive domestic expenditure) generate a trade deficit.
- Below the EB function failure of external balance is not due to a trade deficit but to trade surplus.
- For instance, at point *d*, given the corresponding level D_a of domestic expenditure, the real exchange rate is smaller than the value e'_r required to reach external balance with D_a . That is, the economy is too competitive and therefore runs a trade surplus.

36

Unemployment

Interpreting the EB function /2

37

Unemployment

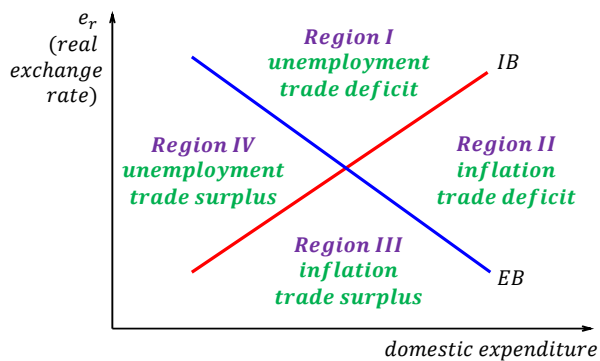

The Swan (or Meade-Swan) diagram

- The Swan diagram (due to Trevor W. Swan) combines the IB and EB functions.
- It separates the plane into four regions.
 - In region I, the economy experiences unemployment and trade deficit (Spain, Egypt, Poland).
 - In region II, inflation coexists with a trade deficit (Brazil, Turkey, Colombia, Morocco).
 - In region III, there is inflation and a trade surplus (China, Russia, Korea).
 - In region IV, the economy has unemployment and runs a trade surplus (Hungary, Slovakia).

38

Unemployment

The Swan diagram

39

Unemployment

The Swan diagram in action

- Suppose the economy is in Region I and, specifically, around the numeral "I" in "Region I".
- At that point, the economy has unemployment. It may appear that more expenditure is needed to reduce unemployment.
- The diagram suggests that the unemployment problem this economy faces is not solved by changing expenditure (increasing it) but by shifting expenditure. To reach the intersection of the IB and EB lines, domestic expenditure must be reduced and net exports increased (through depreciation).

40

Unemployment

Principle of effective market classification

- Robert Mundell's principle of effective market classification: "Policies should be paired with the objectives on which they have the most influence".
- "In countries where employment and balance-of-payments policies are restricted to monetary and fiscal instruments, monetary policy should be reserved for attaining the desired level of the balance of payments and fiscal policy for preserving internal stability. The opposite system would lead to a progressively worsening unemployment and balance-of-payments situation".

<http://robertmundell.net/major-works/the-appropriate-use-of-monetary-and-fiscal-policy-for-internal-and-external-stability>

41

Unemployment

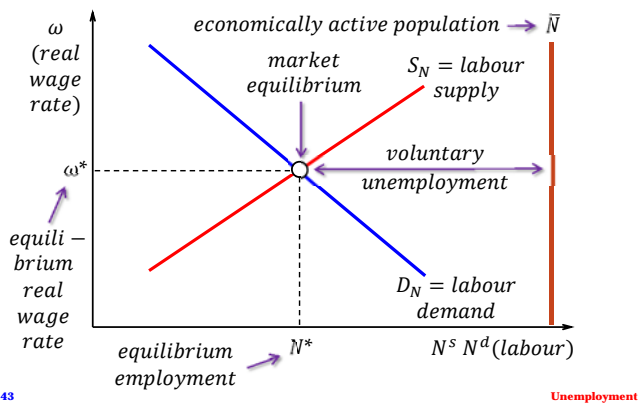

Explaining involuntary unemployment

- Involuntary unemployment occurs when, at the prevailing wage rate in the economy, there are people willing to work but are not given a job.
- The models developed next illustrate basic reasons for the existence of involuntary unemployment:
 - "too high" wage rates (classical explanation);
 - insufficient labour demand, due to insufficient aggregate demand (Keynesian explanation);
 - existence of market power (trade unions);
 - existence of labour discrimination; and
 - structural reasons (last model).

42

Unemployment

The classical labour market model /1

The classical labour market model /2

- It is a standard competitive model in which “price” is represented by the real wage ω (the nominal wage W divided by some price level P) and “quantity” is labour (labour supplied and demanded).
- The higher ω , the higher the labour supply N^S (up to the maximum labour that can be supplied: the economically active population \bar{N}). The labour supply function is therefore increasing.
- The labour demand function is decreasing: the higher ω , the lower the labour demand N^d .

Competitive labour demand /1

- A labour demand function can be constructed as follows. Take any firm using labour n to produce a certain commodity X by means of the production function $q(n)$ that establishes the total amount of X that can be produced using n units of labour.
- Define the firm’s profit function as $\pi(n) = p \cdot q(n) - W \cdot n$, where n is the amount of labour the firm hires, p is the price at which the firm sells X (in a competitive market for X), and W is the nominal wage (the cost of hiring each unit of labour).

Competitive labour demand /2

- Suppose the aim of the firm is to choose n to maximize the profit function. Assuming the function $q(n)$ differentiable, the first order condition for a maximum is $\frac{d\pi(n)}{dn} = 0$. Since the firm is a price taker in the commodity market,
- $$\frac{d\pi(n)}{dn} = p \cdot \frac{dq(n)}{dn} - W = 0 .$$
- The derivative $\frac{dq(n)}{dn}$ is the marginal product of labour (MPL). Therefore, $MPL(n) = W/p$ implicitly defines the firm’s labour demand function.

Competitive labour demand /3

- $MPL(n)$ is typically supposed to be decreasing: the more labour is hired, the smaller the contribution that the last unit makes to production (each additional unit of labour is less productive).
- As a result, when represented graphically in the space $(\frac{W}{p}, n)$, the function $\frac{W}{p} = MPL(n)$ is decreasing. This says that the firm hires labour until its marginal product coincides with the real cost of hiring labour (the real wage $\frac{W}{p}$). Equivalently, labour is paid according to the value of its marginal productivity: $W = p \cdot MPL(n)$.

Example

- If $q(n) = 2 \cdot n^{1/2}$, $MPL(n) = \frac{dq(n)}{dn} = 2 \cdot \frac{1}{2} \cdot (n)^{\frac{1}{2}-1} = n^{-1/2} = \frac{1}{n^{1/2}}$. The firm’s labour demand function is
- $$MPL(n) = \frac{W}{p}$$
- Therefore, $\frac{1}{n^{1/2}} = \frac{W}{p}$. Solving for n ,
- $$n = \frac{1}{(W/p)^2} \text{ or } n = \frac{p^2}{W^2}$$
- Since $\frac{dn}{d(W/p)} = -\frac{2}{(W/p)^3} < 0$, the demand for labour is a decreasing function of the real wage W/p .

Equilibrium in the labour market

- Since the labour demand of each firm is inversely correlated with a certain wage rate, one may jump to the conclusion that the aggregate demand for labour in an economy is inversely correlated with the economy's real wage.
- The equilibrium real wage rate ω^* is such that labour supplied at ω^* equals labour demanded at ω^* . Given ω^* , there is no involuntary unemployment: everyone willing to get hired at ω^* is hired. The difference $\bar{N} - N^*$ can be viewed as voluntary unemployment ($\frac{N^*}{\bar{N}}$ would be the participation rate).

49

Unemployment

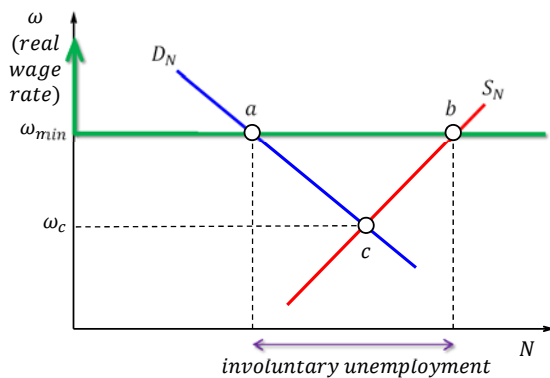

Unemployment in the classical model /1

- Establishing a minimum real wage ω_{min} above the equilibrium wage rate ω^* generates involuntary unemployment in a competitive labour market.
- The next slide illustrates this possibility. Market equilibrium occurs at point c . If the minimum wage rate ω_{min} is set, the market state is no longer represented by c but by a : although workers are willing to be at b , firms cannot be forced to hire more workers than the amount given by a .
- At the prevailing wage rate ω_{min} there is an excess supply, interpreted as involuntary unemployment.

50

Unemployment

Unemployment in the classical model /2

51

Unemployment

Unemployment in the classical model /3

- Involuntary unemployment in a competitive labour market may also temporarily arise if the real wage rate adjusts sluggishly.
- The next slide illustrates this situation. Market equilibrium occurs initially at a , with wage rate ω_a . The demand for labour function shifts to the left. The new equilibrium would be represented by c .
- But if the real wage rate takes time to adjust (decrease), the wage rate in the market may temporarily remain at the initial level ω_a . The market is then at b , where involuntary unemployment exists.

52

Unemployment

Unemployment in the classical model /4

53

Unemployment

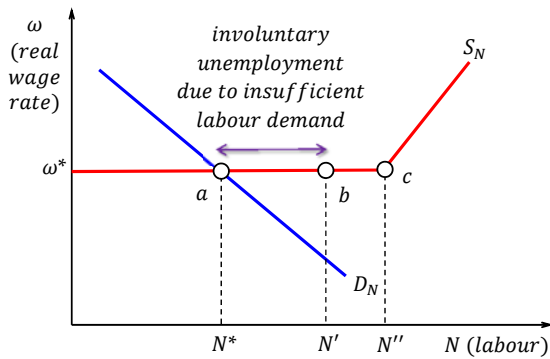

An atypical example /1

- Suppose the S^N function combines a flat with an upward sloping section, as shown in the next slide.
- The flat section at real wage ω^* could be interpreted in the sense that, when the real wage is ω^* , (i) workers are, in principle, indifferent between supplying labour or not, and (ii) some random variable determines the amount actually supplied.
- Market equilibrium occurs at a , where employment is N^* . If workers finally choose to supply N' (effective labour supply represented by b), there is involuntary unemployment given by $N' - N^*$.

54

Unemployment

An atypical example /2

55

Unemployment

(Derived) demand for labour

- Firms do not hire workers because they aim at accumulating workerts. The labour forces is a tool to produce commodities and obtain a profit by selling the commodities produced.
- For that reason, it is said that the demand for labour by firms is a derived demand: it arises as an intermediate step in the process of reaching the firms' final goal, which is making profits.
- Hence, the demand for labour crucially depends on sales expectations: no matter how "cheap" labour is, workers will not be hired if firms do not expect to sell what these workers would produce.

56

Unemployment

Monopsony /1

- Since there are fewer firms than workers and firms typically hire several workers, it seems reasonable to presume that firms enjoy some market power.
- To consider a simple benchmark case, suppose there is a unique firm: a monopsonist. In a monopsony, the buyer (the firm) dictates the terms to the sellers (workers). So suppose the firm chooses the wage rate to maximize profits.
- Assume also that the firm is competitive in the product market (price p of the commodity given) and workers are price-takers (take W and p as given).

57

<http://en.wikipedia.org/wiki/Monopsony>

Unemployment

Monopsony /2

- In a monopoly, the monopolist's problem is to choose a point along the market demand function.
- Similarly, a monopsonist will choose a point along the market labour supply function.
- To see this, consider the supply function S_N depicted on the next slide. A monopsonist cannot choose a point a below S_N : at the corresponding wage rate ω_a labour supply N' is smaller than demand N_a .
- A monopsonist will neither choose a point b above S_N : the firm could get the amount N_b of labour demanded at b at a rate ω' smaller than ω_b .

58

Unemployment

The monopsonist is limited by S_N

59

Unemployment

Monopsony /3

- The firm's profit function is $\pi(N) = p \cdot q(N) - W(N) \cdot N$, where $W(N)$ is the labour supply function (in nominal terms): $W(N)$ is the smallest nominal wage W inducing workers to supply the amount N of labour. Using the chain rule,

$$\frac{d\pi(N)}{dN} = p \cdot \frac{dq(N)}{dN} - \left(\frac{dW(N)}{dN} \cdot N + W(N) \right)$$

- To reach a maximum, it is necessary that $\frac{d\pi(N)}{dN} = 0$.

Accordingly, since $\frac{dq(N)}{dN} = MPL(N)$,

$$p \cdot MPL(N) = W(N) + \frac{dW(N)}{dN} \cdot N$$

60

Unemployment

Monopsony /4

- The left-hand side $p \cdot MPL(N)$ is the marginal revenue of labour or value of the marginal product of labour: the money revenue the firm obtains by selling what an additional unit of labour produces.
- The right-hand side $W(N) + \frac{dW(N)}{dN} \cdot N$ represents the marginal cost of labour: the monetary cost of hiring an additional unit of labour. This cost is higher than the nominal wage rate $W(N)$. In real terms,

$$\underbrace{MPL(N)}_{\text{real marginal revenue}} = \underbrace{\frac{W(N)}{p} + \frac{dW(N)}{dN} \cdot \frac{N}{p}}_{\text{real marginal cost}}$$

61

Unemployment

Monopsony /5

- The left-hand side $MPL(N)$ is what the firm obtains in real terms from one more unit of labour. The right-hand side $\frac{W(N)}{p} + \frac{dW(N)}{dN} \cdot \frac{N}{p}$ is what one more unit of labour costs to the firm in real terms.
- When the firm is competitive (wage taker), the condition is $MPL(N) = \frac{W}{p}$, so the real wage $\frac{W}{p}$ defines the real marginal cost for the firm. But, for a monopsonist, this cost is higher than the real wage $\frac{W(N)}{p}$, for which reason the real marginal cost function $MC(N)$ lies above the supply function S_N .

62

Unemployment

Perfect competition vs monopsony

63

Unemployment

Example

- Let $q(N) = 15 \cdot N - \frac{1}{2}N^2$, with $q(N) = 0$ if $N > 24$, be the monopsonist's production function. The labour supply function is $N = \frac{1}{2} \frac{W}{p}$; that is, $W = 2 \cdot N \cdot p$. Since $\pi = p \cdot \left(15 \cdot N - \frac{1}{2}N^2\right) - (2 \cdot N \cdot p) \cdot N$, $\frac{d\pi}{dN} = p \cdot (15 - N) - 4 \cdot N \cdot p$. Therefore, $\frac{d\pi}{dN} = 0$ implies $15 - N = 4 \cdot N$. The monopsonist demands $N = 3$ ($W/p = 6$). If the firm is competitive, labour demand is obtained from $PML = \frac{W}{p}$, where W comes from the labour supply function. In sum, $15 - N = \frac{2 \cdot N \cdot p}{p}$ and $N = 5$ ($W/p = 10$).

64

Unemployment

On the monopsony solution

- The monopsony solution, in analogy with the monopoly solution, is determined in two stages. First, marginal cost of labour is equated to marginal revenue of labour (point a) to ascertain the labour demanded N_m . Second, the wage rate ω_m chosen by the monopsonist is the one that the supply of labour associates with N_m .
- The result is not involuntary unemployment (given ω_m , workers would like to supply precisely N_m) but what could be considered underemployment: the compensation workers receive may be too low compared with their ability (their MPL).

65

Unemployment

Supply-side market power: unions /1

- The monopsony analysis shows that demand-side market power generates less employment and lower wages than perfect competition.
- Supply-side market power is typically associated with the existence of trade unions. For any given amount of labour N , the wage rate unions demand to supply N will be higher than the wage rate dictated by the supply of labour function.
- This follows from the fact that unions (since they can organize strikes) have more bargaining power over wages than individual workers.

66

Unemployment

Supply-side market power: unions /2

- As a result, the function S_{UNIONS} associating with each amount of labour N the wage rate that unions will ask to be willing to supply N must lie above the supply of labour function.
- The next slide combines the function S_{UNIONS} with a competitive labour demand function D_N . Without trade unions, market equilibrium is at c . With unions market equilibrium is at u . The distance between u and v represents involuntary unemployment: given wage ω_u , workers would individually like to supply N_v but the presence of the union only allows N_u to be hired.

67

Unemployment

Supply-side market power: unions /3

68

Unemployment

Fighting involuntary unemployment

- When the wage is “too high”, the obvious solution to get rid of unemployment is to lower the wage (or let time pass by for the wage to adjust by itself).
- When unemployment is due to lack of labour demand, the natural solution is an aggregate demand expansion that induces firms to hire more workers to satisfy the additional demand.
- When the cause of unemployment is market power (unions), the solution seems harder to implement: how to reduce the unions’ bargaining power without raising protests by part of the workers?

http://en.wikipedia.org/wiki/Trade_unions_in_the_United_Kingdom

69

Unemployment

Price setting & wage setting model /1

- In modern economies, the nominal wage rate of a substantial number of workers is determined through collective bargaining involving unions.
- If workers are represented by unions, at any level of employment, the real wage will be above the wage rate dictated by the labour supply function.
- It is assumed that unions establish the real wage using a wage setting function WS sloping upward and lying above the labour supply function S_N . The higher the unions’ bargaining power, the larger the vertical distance between between WS and S_N .

70

Unemployment

Price setting & wage setting model /2

- Whereas workers (through unions) are assumed to set the nominal wage, firms are supposed to fix the prices of the commodities they produce.
- A simple price setting rule consists of adding a mark-up $\hat{\mu} > 0$ to labour costs: $P = (1 + \hat{\mu}) \cdot \frac{W}{MPL}$.
- W is measured in money (EUR) and MPL in units of product per worker. Thus, $\frac{W}{MPL}$ is the money paid to workers divided by what they produce. In other words, $\frac{W}{MPL}$ is the (labour) cost of producing a unit of the commodity.

71

Unemployment

Price setting & wage setting model /3

- It is convenient to define $\mu = \frac{\hat{\mu}}{1 + \hat{\mu}}$, so $P = (1 + \hat{\mu}) \cdot \frac{W}{MPL}$ can be equivalently expressed as $P = \frac{1}{1 - \mu} \cdot \frac{W}{MPL}$.
- Clearly, $(1 - \mu) \cdot MPL = \frac{W}{p}$. In sum,

$$\underbrace{MPL}_{\text{production per worker}} = \underbrace{\frac{W}{p}}_{\text{real wage per worker}} + \underbrace{\mu \cdot MPL}_{\text{real profit per worker}}$$
- μ is then a mark-up over output: the fraction of the workers’ productivity that the firm appropriates.

72

Unemployment

Price setting & wage setting model /4

- Under perfect competition in the labour and product markets, $\frac{W}{p} = MPL$.
- When prices are set by firms as the marking up of labour costs per worker, $\frac{W}{p} = (1 - \mu) \cdot MPL$. This is called the price setting function PS. As $0 < \mu < 1$, $\frac{W}{p} = (1 - \mu) \cdot MPL$ means that $\frac{W}{p} < MPL$.
- As the *MPL* function is downward sloping, the *PS* function is downward sloping as well. *PS* lies below MPL because *PS* is a fraction of *MPL* (the constant $1 - \mu$ is smaller than 1).

73

Unemployment

The WS and PS model

74

Unemployment

Example

- Supply of labour function: $\omega = \frac{5}{3} \cdot N$ (ω is the real wage rate).
- *MPL* function: $MPL = 20 - 5 \cdot N$.
- Demand for labour function: $\omega = MPL$.
- *WS* function: $\omega = 3 \cdot N$.
- *PS* function: $\omega = (1 - \mu) \cdot MPL$, with $\mu = 0.4$.
- Competitive solution: $\frac{5}{3} \cdot N = 20 - 5 \cdot N \Rightarrow N = 3$ and $\omega = 5$.
- *WS* - *PS* solution: $3 \cdot N = 0.6 \cdot MPL \Rightarrow 3 \cdot N = 0.6 \cdot (20 - 5 \cdot N) \Rightarrow N = 2$ and $\omega = 6$.

75

Unemployment

Segmented labour market model

- Suppose workers may have or not some economically irrelevant feature that firms may like or not (for instance, being a man or not).
- Firms classify workers in two types (I and II) depending on whether they possess the feature or not. Some firms (type I firms) prefer type I workers; the rest (type II) prefer type II workers.
- Each type of firms defines a different (competitive) labour market. Workers are unaware of the fact that there are two types of firms. From their perspective, the labour market is not segmented.

76

Unemployment

Example /1

- Supply of labour function of type I workers: $S_N^I = 4 \cdot \omega$ (ω is the real wage rate).
- Demand for labour function of type I firms: $D_N^I = 60 - 2 \cdot \omega$ ($N_N^d = 0$ if $\omega > 30$).
- Market equilibrium (type I): $(N_I, \omega_I) = (40, 10)$.
- Supply of labour function of type II workers: $S_N^{II} = 12 \cdot \omega$.
- Demand for labour function of type II firms: $D_N^{II} = 80 - 4 \cdot \omega$ ($N_N^d = 0$ if $\omega > 20$).
- Market equilibrium (type II): $(N_{II}, \omega_{II}) = (60, 5)$.

77

Unemployment

Example /2

- $\frac{40}{40+60} = \frac{2}{5} = 40\%$ of employment corresponds to type I workers and $\frac{60}{40+60} = \frac{3}{5} = 60\%$ to type II. Using these weights, the average real wage rate would be $\tilde{\omega} = \frac{2}{5} \cdot \omega_I + \frac{3}{5} \cdot \omega_{II} = \frac{2}{5} \cdot 10 + \frac{3}{5} \cdot 5 = 7$.
- At $\tilde{\omega} = 7$, no more type I workers than are actually employed would like to be hired. But, at $\tilde{\omega} = 7$, type II workers would like to supply $S_N^{II} = 12 \cdot \tilde{\omega} = 84$. Since employment of type II workers equals $N_{II} = 60$, involuntary unemployment appears to be $S_N^{II}(\tilde{\omega} = 7) - N_{II} = 84 - 60 = 24$ (unemployment rate = $24 / (24 + N_I + N_{II}) = 19.3\%$); see next slide.

78

Unemployment

Though each segment is in equilibrium, there is a sense in which involuntary unemployment exists.

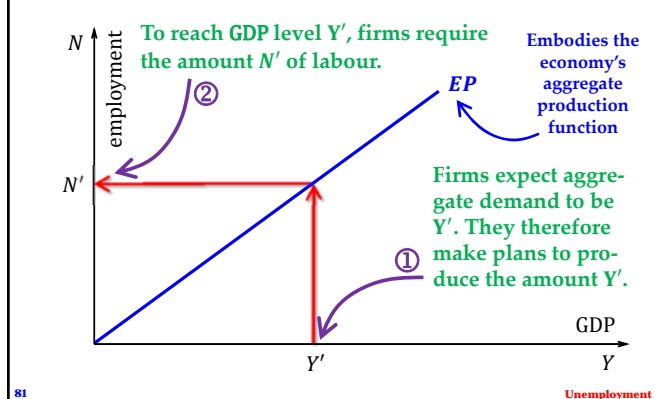

The E-PIS model

- It postulates three linear relations linking employment with production, income, and spending.
 - EP** relation (production → employment): establishes the amount of employment required to reach a certain GDP level.
 - EI** relation (income → employment): identifies the amount of labour supplied for every value of aggregate income.
 - ES** relation (employment → expenditure): indicates the aggregate level of spending associated with any given amount of employment.

80 Unemployment

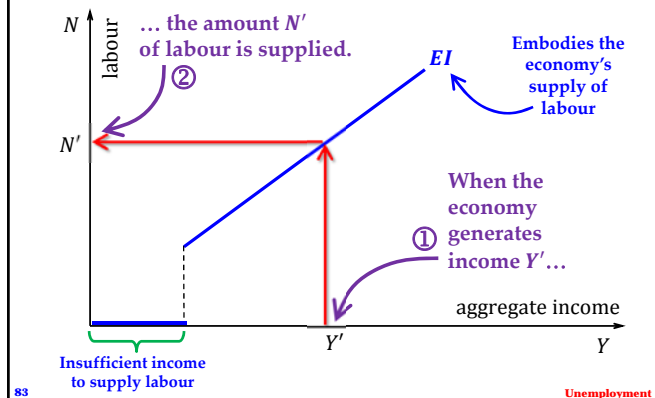

EP (employment-production) relation

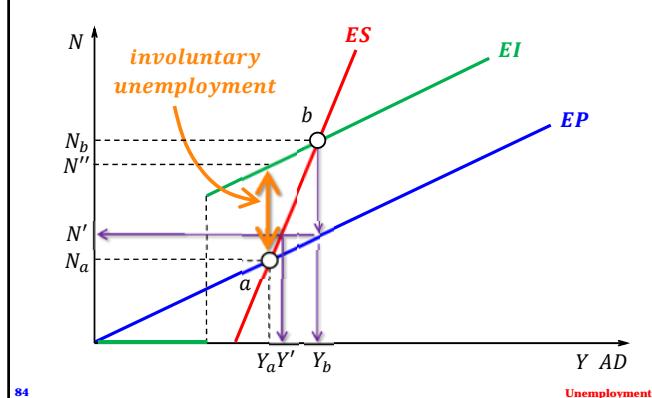

ES (employment-spending) relation

EI (employment-income) relation

Solving the E-PIS model /1

Solving the E-PIS model /2

- When drawn simultaneously, there is no point at which the three relations intersect.
- Without delving into details, let us assume that the solution is found at a point when two lines intersect. Leaving the origin aside, there are two candidates: point a and point b .
- Point b is not stable (self-sustained). At b , employment is N_b and aggregate demand is Y_b . But, according to EP , to produce Y_b , the economy only needs the amount $N' < N_b$ of labour. Hence, b does not represent a consistent state of the economy.

85

Unemployment

Solving the E-PIS model /3

- At a , employment is N_a and aggregate demand is Y_a . To generate a GDP equal to Y_a firms demand exactly the amount N_a of labour. In addition, the level N_a of employment generates precisely the level Y_a of aggregate demand. This state of the economy appears self-consistent and stable.
- The problem is that there is involuntary unemployment at point a . Given income Y_a , workers would like to supply the amount N'' of labour. Since employment at a is only N_a , $N'' - N_a$ defines the level of involuntary unemployment. Question: what shifts in the lines would reduce it?

86

Unemployment

Interpreting the E-PIS model /1

- The arguably simplest description of an economy is given by the loop
production → income → expenditure → production → ...
- The E-PIS model inserts labour in this loop. First, production creates a derived demand: the demand for labour. Second, the income the economy generates is a key variable helping workers to decide the amount of labour supplied.
- Lastly, the level of employment, once determined, significantly contributes to establish aggregate demand, which in turn affects production.

87

Unemployment

88

Unemployment

Interpreting the E-PIS model /2

- The classical view of this process attributes to the labour market the leading role. Employment is first established, this next determines production, and production is finally used.
- The Keynesian view inverts the order. First, expenditure decisions are made. These decisions indicate the necessary production level. Finally, the labour required to carry out the production plan is hired.
- The E-PIS model aligns itself with the latter view. The state of the economy is foremost determined by the firms' expected level of aggregate demand.

89

Unemployment

Interpreting the E-PIS model /3

- To meet the expected demand level Y , firms hire the amount of labour N necessary to produce Y . As long as the income level corresponding to production level Y induces workers to supply at least N , the employment-income relation is irrelevant.
- Since there is no obvious reason why the EI relation cannot be established independently of the other relations, it is highly unlikely that workers will exactly supply N . Thus, the excess of labour supplied constitutes involuntary unemployment. As it emerges from the very working of the economy, it will be hard to eliminate it completely.
